- **Background + Motivation**
- **Methods**
- **Experiments**
- **Results**
- **Conclusion**

- Frequency modulated continuous wave (FMCW) radar can be used to get vital sign information remotely

Phase Extraction

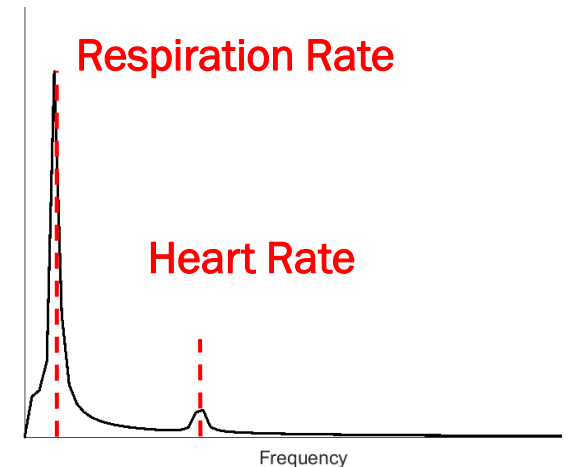

FFT

Ideal Scenario

Respiration Rate

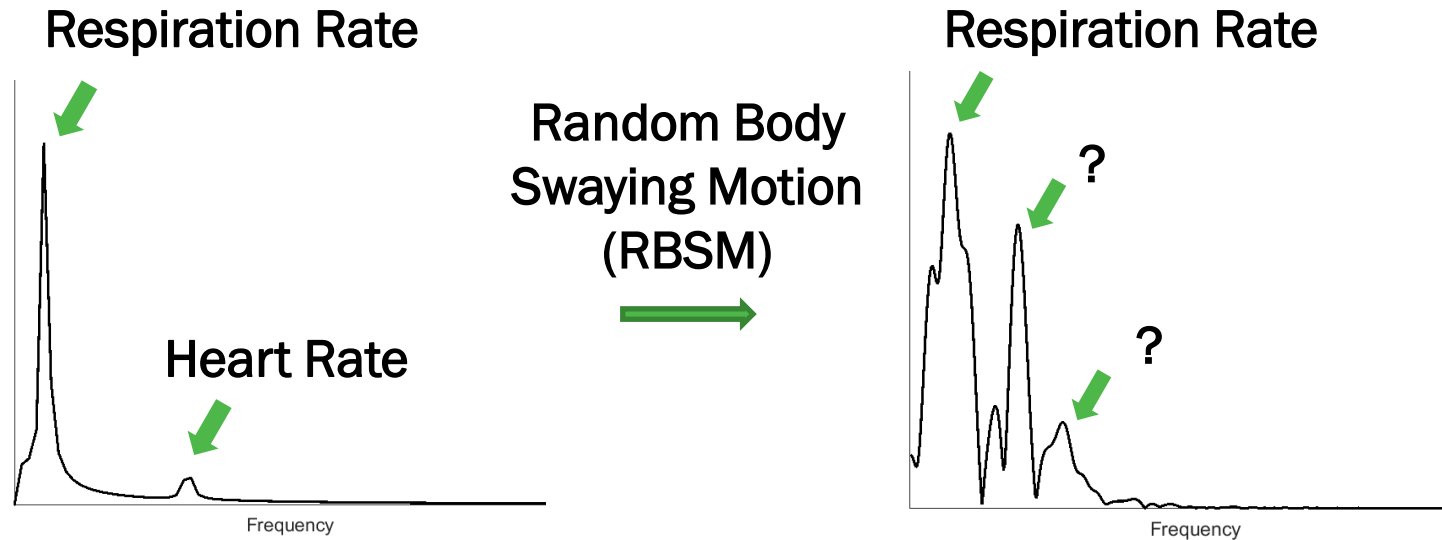

Heart Rate

- Simple:

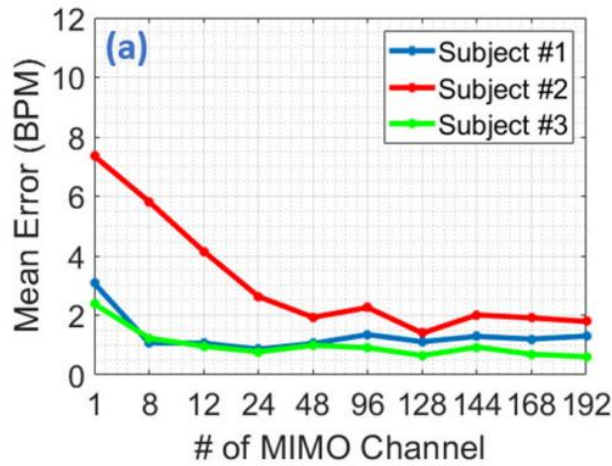

- More Complicated:

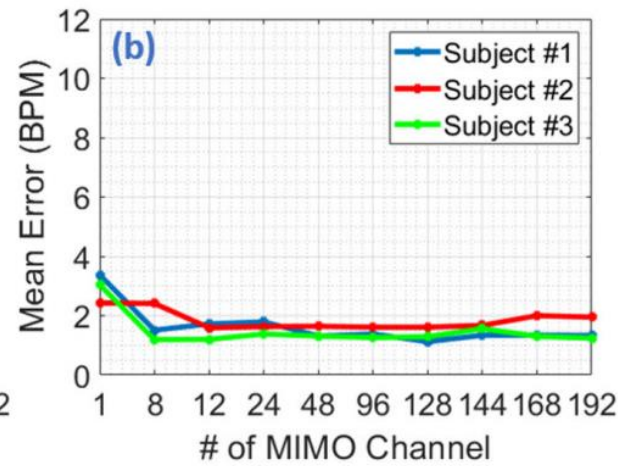

- How do we deal with this RBSM?
- How to deal with respiration harmonics?

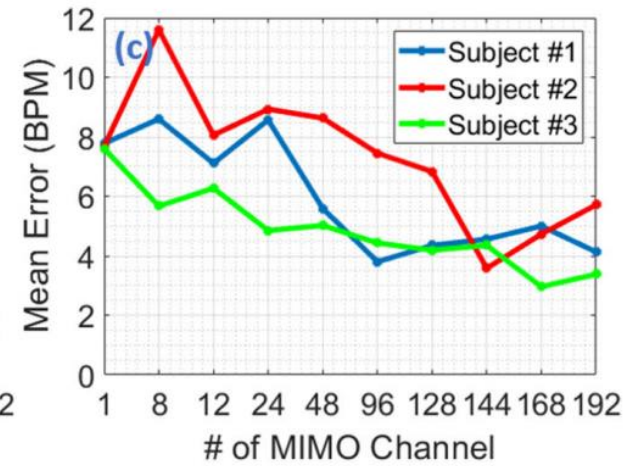

- Has been shown that performance improves as the number of MIMO channels used increases when addressing RBSM in standing subjects
- With more channels comes the need to optimally combine information (and increased computation time)

0.5m

1m

1.5m

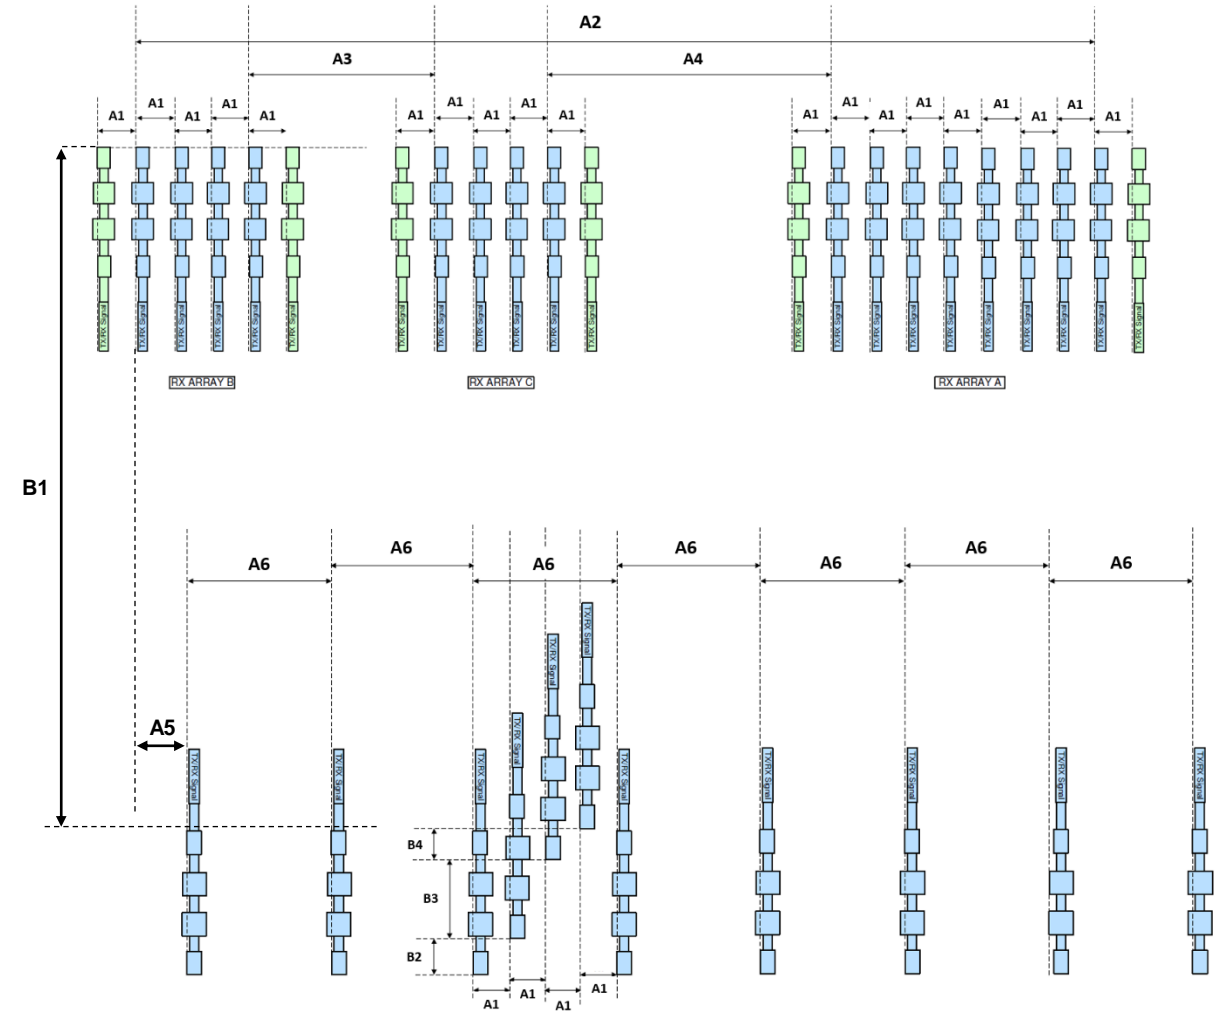

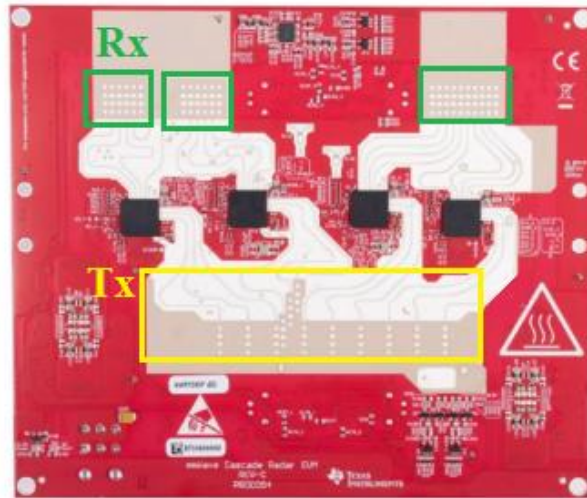

- Maximal Ratio Combining (MRC) is a signal processing technique used to combine data from multiple channels to increase the signal-to-noise ratio (SNR)
- Channel selection as a preprocessing step to MRC is a way to further improve results
 - Only include “good channels” in the final summation
 - Difficult to classify good channels vs. bad channels automatically

$$\phi_{MRC}(t) = \sum_{i=1}^N w_i \phi_i(t)$$

Goal

- Develop a convolutional neural network (CNN)-based framework to automatically classify the MIMO channels of a 192 channel 77GHz FMCW radar as either good or bad based on both time and frequency information
- This will aid MRC in the summation of phase variation signals with the goal of improving heart rate estimation accuracy of standing subjects

- MMWCAS-RF-EVM from TI used in this study
- 192 Total Tx/Rx Channels

Methods – Chirp Configuration

Chirp Parameters	
Start Frequency, f_c (GHz)	77
Frequency Slope, S (MHz/ μ s)	98
Idle Time (μ s)	250
TX Start Time (μ s)	1
ADC Start Time (μ s)	10
ADC Samples	64
ADC Sampling Frequency (MHz)	2.2
Ramp End Time (μ s)	40
Number of Chirp Per Frame	8
Slow-time Sampling Frequency, $f_s = 1/T_s$ (Hz)	20

Detectable Range & Velocity Parameters	
Maximum detectable range (m)	3.3
Range resolution (cm)	3.83
Maximum detectable velocity (m/s)	31
Velocity resolution (m/s)	7.9

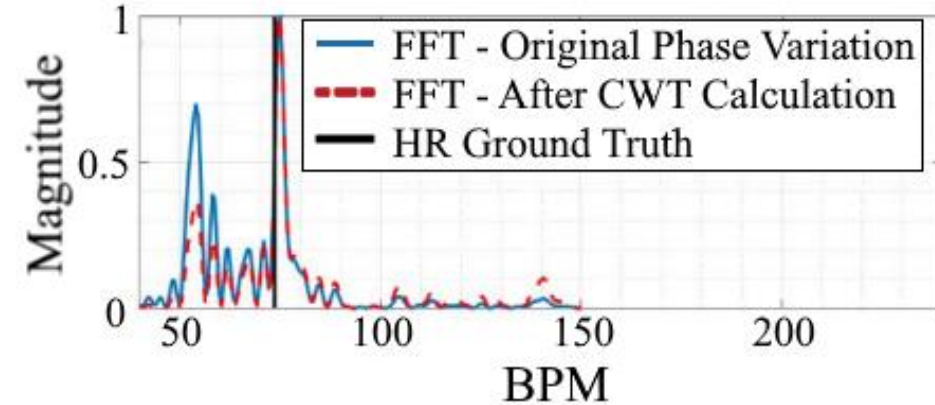

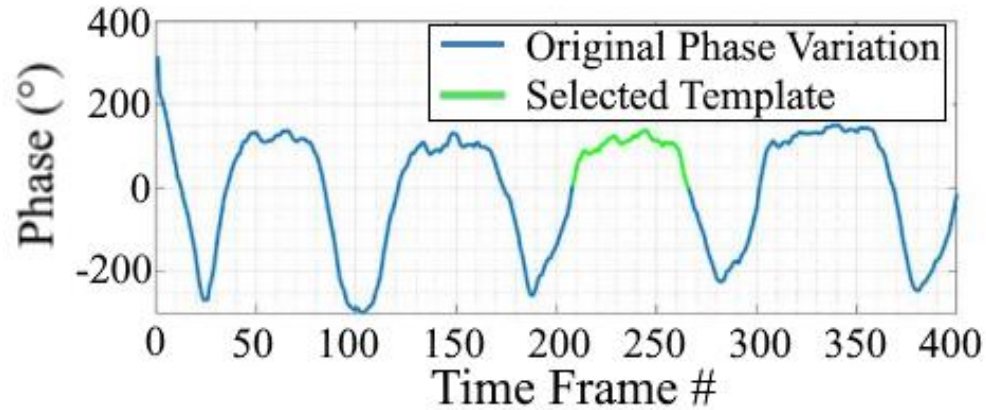

- **Maximal Ratio Combining (MRC):** Weighted average of different MIMO channels

$$\phi_{MRC}(t) = \sum_{i=1}^N w_i \phi_i(t)$$

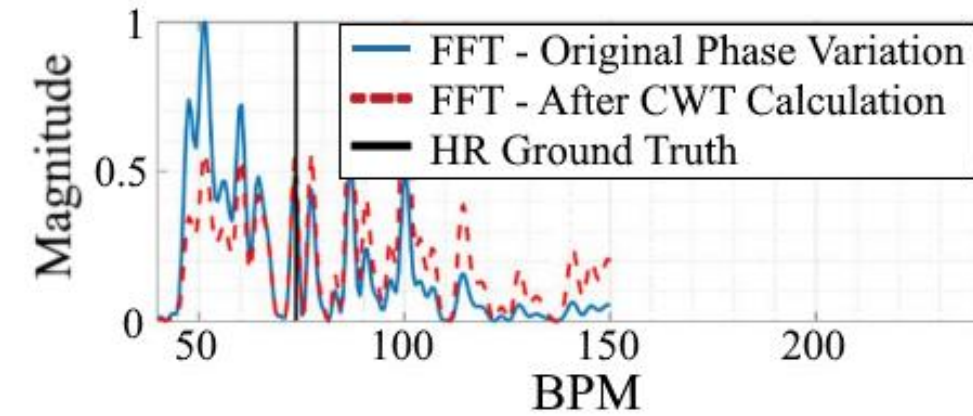

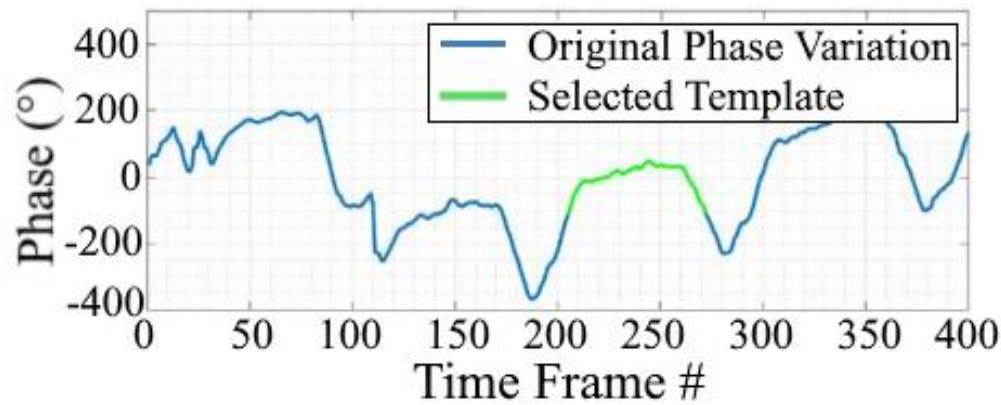

- To determine w_i , a cross-correlation matrix is formed based on the time domain signals channels $\phi(t) = [\phi_1(t), \phi_2(t), \dots, \phi_N(t)]$

$$R_{ij} \simeq \int \phi_i(t) \phi_j^*(t) dt = [v_1 v_2 \dots v_N] \text{diag}[\sigma_1 \sigma_2 \dots \sigma_N] [v_1^* v_2^* \dots v_N^*]^T$$

where σ_{1-N} are the eigenvalues and v_{1-N} are the eigenvectors for N channels. This MRC method uses the first eigenvector as weights for the received signal on all TX-RX pairs such that $\mathbf{w} = \mathbf{v}_1^H$

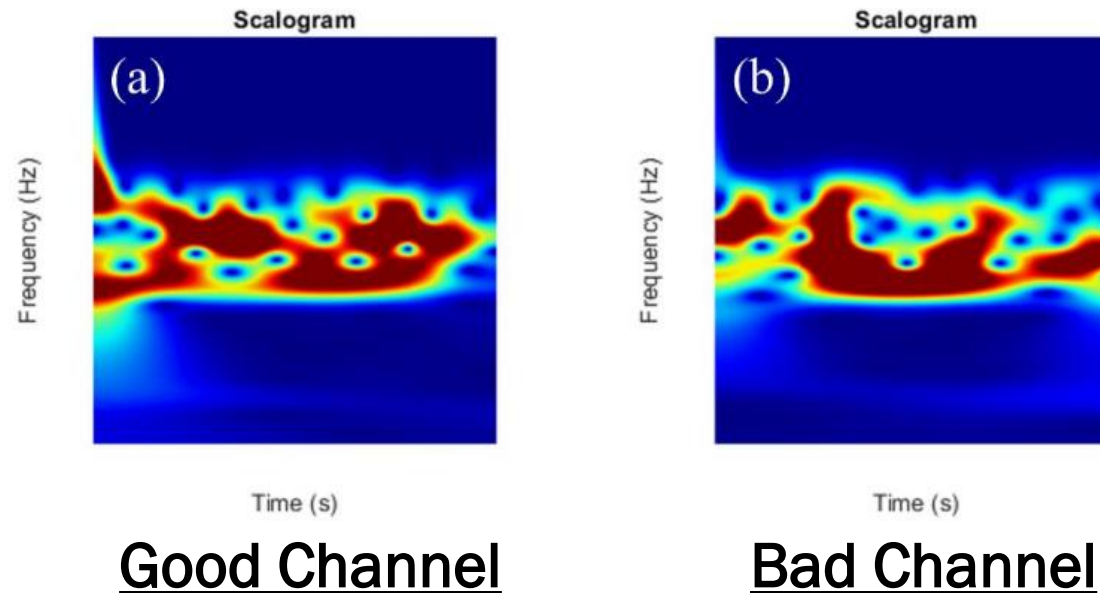

Good Channel

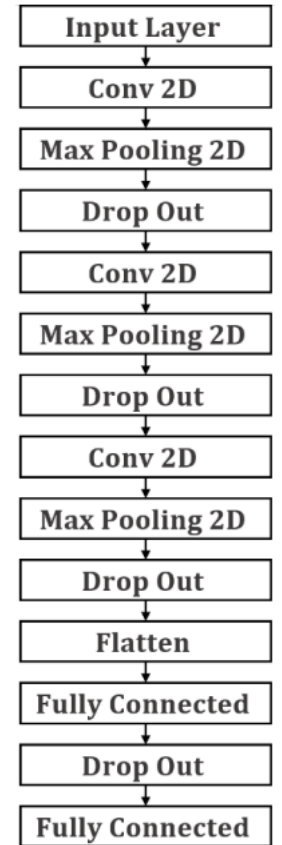

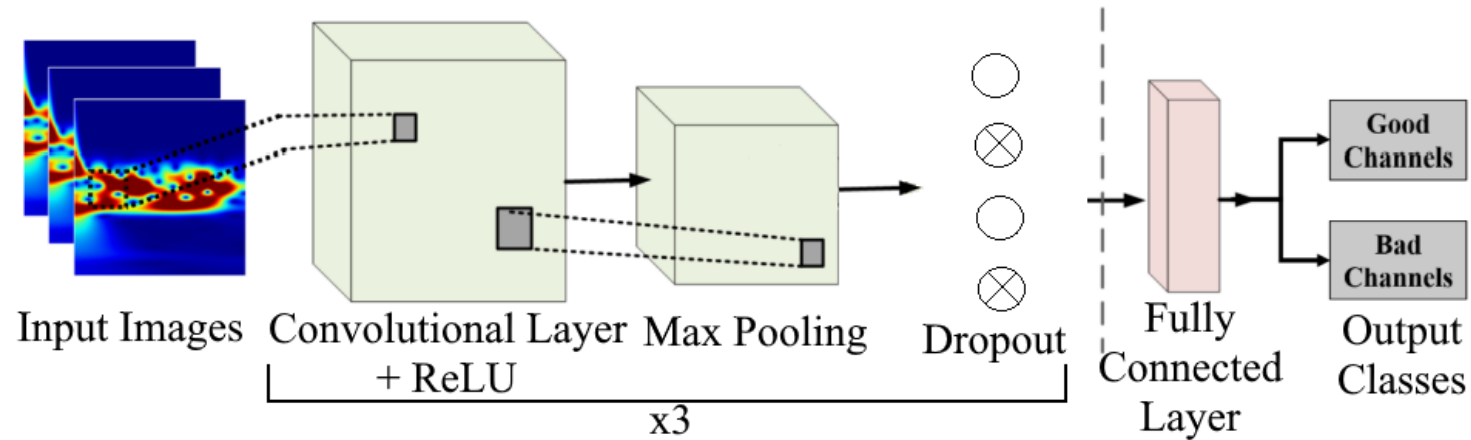

Bad Channel

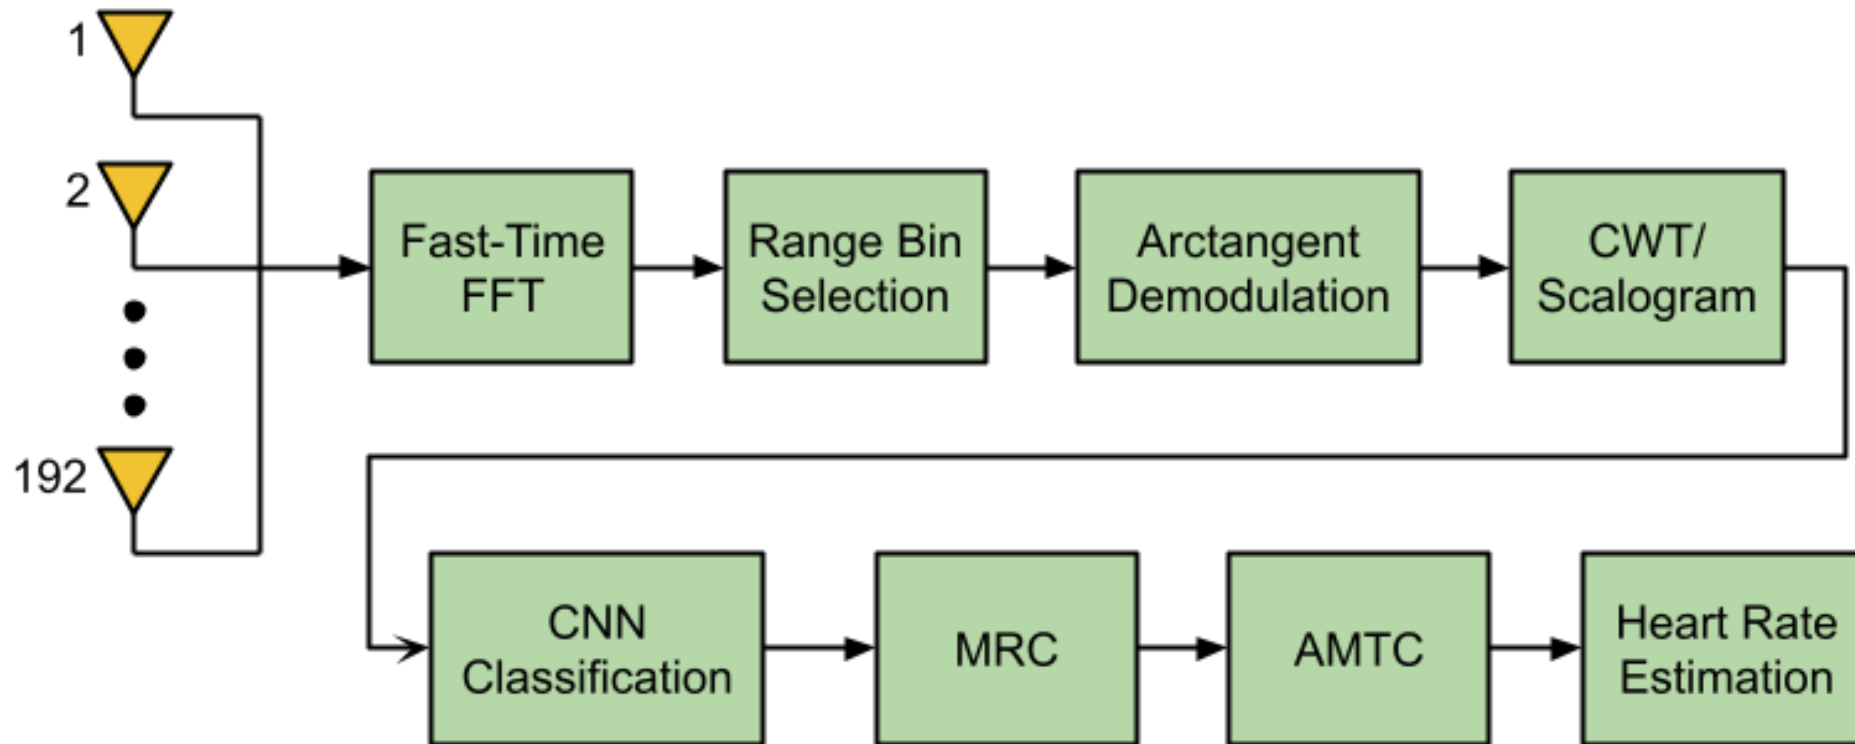

- Time-frequency features are extracted from the phase variation signals of each channel through scalograms using the continuous wavelet transform (CWT)
- Images are resized to be 224x224 pixels with 3 channels representing red, green and blue

- A typical CNN such as the one proposed in [1] can be used.
- The input layer takes in a $224 \times 224 \times 3$ image representing 20 seconds of radar data for a single transmit-receive channel.

Experimental Setup

Participant #	Gender	Age	Weight (lbs)	Height (in)
1	Male	29	125	64
2	Female	30	110	62
3	Male	22	185	70
4	Male	26	150	69
5	Female	54	150	61
6	Female	65	110	64
7	Female	64	235	67
8	Male	23	170	72
9	Male	33	340	73
10	Male	27	125	66
Mean \pm Std	-	37 \pm 17	170 \pm 71	66.8 \pm 4

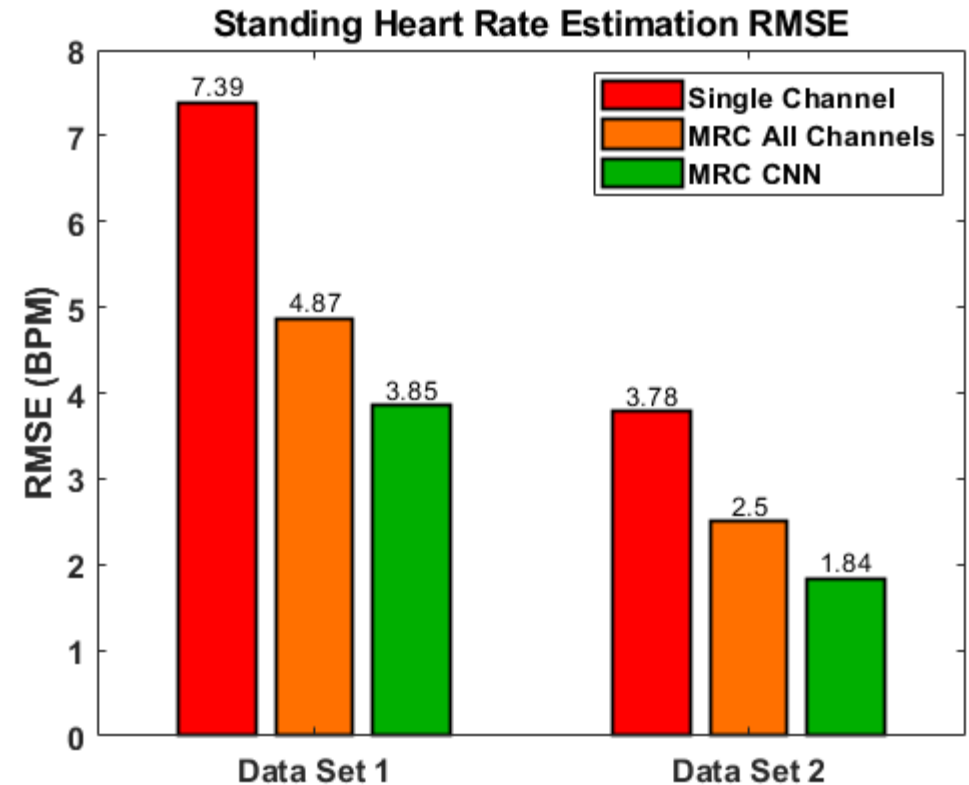

Results – Network Performance

Training Hyperparameters

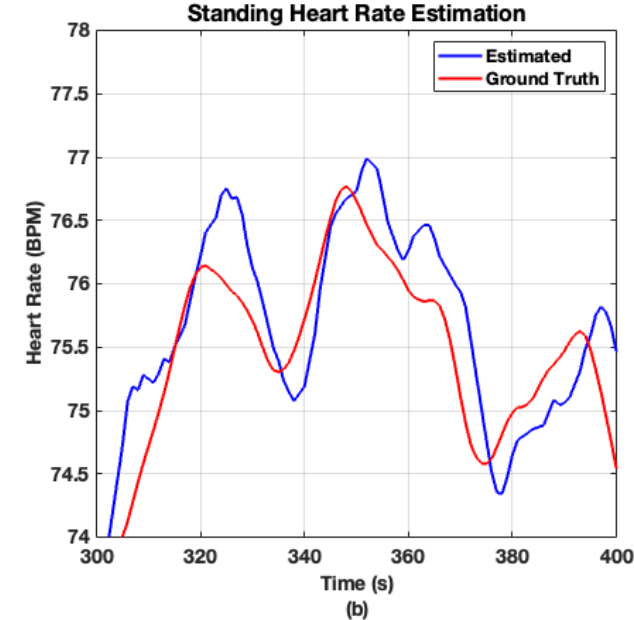

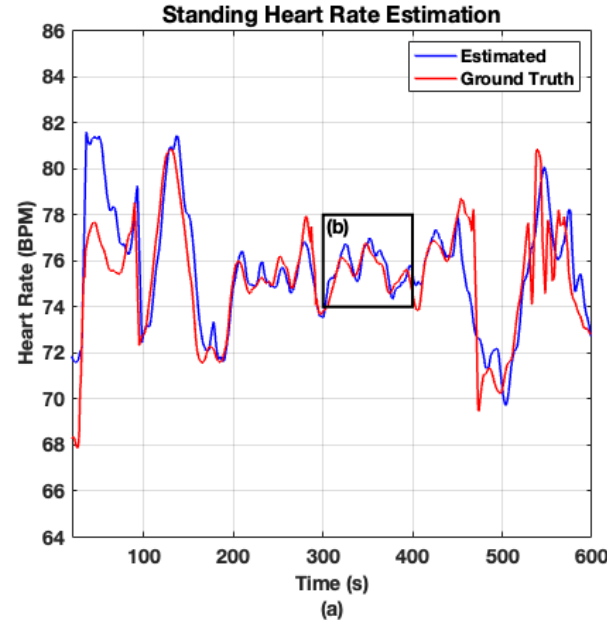

Parameter	Value
Optimizer	Stochastic Gradient Descent
Learning Rate	0.001
Momentum	0.9
Mini Batch Size	16
Epochs	20

- Results show an improvement in heart rate estimation error when only including “good channels” in the MRC summation
- Over 20% improvement when compared to using all channels
- Much greater improvement compared to using a single channel radar

- An example of the estimation accuracy over time is shown for Data Set 2
- It can be seen that the highly varying heart rate of a person standing for 5 minutes can be accurately tracked over the entirety of the experiment.

- It is desired to improve the channel classification accuracy through network improvements
- Apply this technique to a wider range of highly challenging scenarios (walking)
- Possibility of feeding raw I and Q data rather than scalogram images

Conclusion

- A CNN-based method for an automatic process of MIMO channel selection for a mmWave radar was presented to improve remote heart rate estimation accuracy in scenarios containing RBSM
- A channel classification accuracy of over 80% was obtained, allowing for the improvement of the channel summation done by MRC and outperforming the single-channel radar technique
- The heart rate estimation accuracy results of two long-duration standing subject data sets were shown to improve after the use of the trained CNN model by over 20%
